FLOOD INSURANCE STUDY
COOK COUNTY, ILLINOIS

1.0 INTRODUCTION

1.1 Purpose of Study

The purpose of this Flood Insurance Study is to investigate the existence and severity of flood hazards in the unincorporated areas of Cook County, Illinois, and to aid in the administration of the National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973. Initial use of this information will be to convert unincorporated Cook County to the regular program of flood insurance by the Federal Insurance Administration (FIA). Further use of the information will be made by local and regional planners in their efforts to promote sound land use and flood plain development.

1.2 Coordination

Identification of streams to be studied in detail and streams to be studied by approximate methods was done at meetings attended by personnel of Harza Engineering Company (the study contractor), the FIA, and the State of Illinois, Department of Transportation, Division of Water Resources (DOWR). Hydrologic and hydraulic analyses were coordinated with the U. S. Army Corps of Engineers (COE); the U. S. Department of Agriculture, Soil Conservation Service (SCS); the U. S. Department of Agriculture, Forest Service; the U. S. Geological Survey (USGS); the Metropolitan Sanitary District of Greater Chicago (MSDGC); the State of Illinois, Departments of Conservation and Transportation; the Cook County Forest Preserve District; and steering committees represented by municipal governments.

Historic flood information, high-water information, and flow data used for flood frequency studies were obtained from the USGS. Climatic data were obtained from National Oceanic and Atmospheric Administration publications.

During the course of the work, flood elevations, flood boundaries, and floodway delineations were reviewed by officials of the DOWR, and the FIA. On December 13, 14, and 15, 1977, results of the work were reviewed at three final Consultation and Coordination Officer's (CCO) meetings attended by representatives of the FIA and the study contractor, and community and state officials.

1.3 Authority and Acknowledgements

The source of authority for this Flood Insurance Study is the National Flood Insurance Act of 1968, as amended.

The hydrologic and hydraulic analyses for this study were prepared by Harza Engineering Company for the Federal Insurance Administration, under Contract No. H-3809. This work, which was completed in September 1976, covered all significant flooding sources in the unincorporated areas of Cook County, Illinois.

2.0 AREA STUDIED

2.1 Scope of Study

This Flood Insurance Study covers the unincorporated areas of Cook County, Illinois. Not included in this study are the incorporated portions of the county, such as villages, townships, and cities. The area of study is shown on the Vicinity Map (Figure 1).

Detailed methods were used to study 60 streams in the subject area. These detailed-study streams are listed below.

West Fork of North Branch Chicago River

For the incorporated communities within Cook County that exercise extraterritorial jurisdiction, the flood boundaries and floodways have been identified and delineated in this study. The only exception is for the Village of Arlington Heights in Cook County. The areas of extraterritorial jurisdiction for Arlington Heights are shown in the Flood Insurance Study for the village, published in May 1978, and the present study excludes these areas.

Many of these streams pass into and out of several incorporated areas along their courses; however, only the stream segments located in the unincorporated areas of the county are described in this report. The areas studied by detailed methods were selected with priority given to all known flood hazard areas and areas of projected development and proposed construction for the next five years, through September 1981.

Portions of the main stems and tributaries from major drainage networks within Cook County were studied by approximate methods. These networks include: North Branch Chicago River, Salt Creek, Des Plaines River, Poplar Creek, and Little Calumet River. Other approximate study areas include portions of Higgins Creek, Lansing Ditch, Tributary A of Thorn Creek, Wheeling Drainage Ditch, Butterfield Creek, Butterfield Creek East Branch, Tributary of Butterfield Creek East Branch, West Branch DuPage River, Addison Creek, Chicago Sanitary Drainage and Ship Canal, Calumet Sag Channel, Tributary A of Calumet Sag Channel, Goose Lake, Tinley Creek, Midlothian Creek, Midlothian Creek Tributary, North Creek, Spring Creek, Tributary D of Marley Creek, Tributary of Union Drainage Ditch, Western Branch

Midlothian Creek, Union Drainage Ditch, Flossmoor Ditch, Thorn Creek, Mill Creek, Tributary A of Mill Creek, Orland Lake, Lord's Park Tributary, Tributary A of Long Run, Skokie River, Skokie Ditch, Skokie Lagoons, Silver Creek, Willow Creek, Axehead Lake, Feehanville Ditch, Farmer's Creek, White Pine Ditch, Baker Lake, Merrionette Park Ditch, Saganashkee Slough, Tributary B of Calumet Sag Channel, Belly Deep Slough, and other unnamed streams located in Cook County. Approximate methods of analysis were used to study those areas having low development potential and minimal flood hazards as identified at the initiation of the study. The scope and methods of study were proposed to and agreed upon by the FIA.

2.2 Community Description

Cook County is situated in northeastern Illinois. The county has a total area of 938 square miles, of which about 25 percent is unincorporated. This area is undergoing rapid urbanization, which could mean more flood-damage problems than in the past along the streams studied in this report.

Temperature data are published for 13 climatological stations in Cook County; however, all of these stations are in the metropolitan Chicago area (Reference 1). Data for the station at Chicago's Midway Airport are typical for these stations and for the county as well. The average annual temperature at Midway Airport is 50.8 degrees Fahrenheit (°F), with average January temperatures of 26°F and average July temperatures of 76°F. Average annual precipitation at the Midway Airport gage is 33.2 inches.

The North Branch Chicago River is the main drainage feature for many of the northern suburban communities of Chicago. The North Branch flows southeasterly through many incorporated areas to join the South Branch in downtown Chicago. The study reaches are located in the northeastern corner of Cook County, where there are intermittent reaches flowing through unincorporated land.

Salt Creek is a tributary of the Des Plaines River; it flows southward from Palatine to Oak Brook, then eastward to its confluence with the Des Plaines River within Lyons. The unincorporated areas being investigated in the Salt Creek watershed are adjacent to the communities of Addison, Elk Grove Village, Rolling Meadows, and Inverness. Study reaches on the West Branch of Salt Creek are intermittent with the corporate boundaries of Schaumburg.

The Des Plaines River parallels the North Branch Chicago River, which is located 5.5 miles to the east, for the first 12 miles of its southerly path through Cook County. The Des Plaines River

continues south for another 14 miles to the vicinity of the Chicago Sanitary and Ship Canal; it then flows southwestward, parallel to the canal. Seven major tributaries of the Des Plaines River and seven second-order tributaries are considered in this report. These tributaries are located along the entire course of the Des Plaines River flood plain, just outside the limits of several incorporated suburban communities.

Another major drainage feature is Poplar Creek, which drains northwestern Cook County and flows southwestward into the Fox River near Elgin in Kane County. Four segments of the main stream of Poplar Creek were selected for analysis: between the Kane-Cook County line and Elgin, between Elgin and Hoffman Estates, between Hoffman Estates and South Barrington, and between South Barrington and Barrington Hills. The South Branch of Poplar Creek was studied from its confluence with Poplar Creek to Streamwood. The Schaumburg Branch of Poplar Creek was studied from the confluence with Poplar Creek to the Northwest Tollway.

The major tributary of the Little Calumet River considered in this report is Thorn Creek, which flows northwestward from the Cook-Will County line and joins the Little Calumet River in South Holland, a distance of about 12 stream miles. Thorn Creek flows through the incorporated municipalities of South Chicago Heights, Chicago Heights, Glenwood, and South Holland; only the extreme upstream reach in Cook County and a small reach near Interstate 80 are located in unincorporated areas. Five major tributaries and one second-order tributary of Thorn Creek were studied also. These tributaries drain unincorporated areas which are under residential urbanization pressure from seven surrounding suburban communities. A 2.29-mile reach of Plum Creek which crosses the extreme southeast corner of Cook County is included in this study; the undeveloped drainage area of Plum Creek is located near Sauk Village, and residential urbanization is expected within the next five years.

Nine principal streams and several second- and third-order tributaries were grouped for purposes of discussion and analysis; these streams are located in southwest Cook County in unincorporated areas that are not yet developed, but are expected to have significant residential development in the next five years. The area containing these streams is bounded by the county line, the Illinois and Michigan Canal, and the Calumet Sag Channel.

2.3 Principal Flood Problems

In unincorporated areas of Cook County, flood peaks have been increasing because of recent urbanization of the uplands, with

resultant greater runoff. Urbanization often is accompanied by filling in the flood plain or by encroachment upon it, which reduces channel conveyance capacity. Increased floods on the main channels cause backwater effects up their tributaries. Additional flood runoff is unable to flow through restricted culverts and bridge openings, which often are clogged with sediment and debris from new construction. The problems associated with urbanization are further complicated by inadequate channel improvements.

Flood damages include residential damage, some business and commercial damage, road closures with corresponding transportation disruption, school closures, and agricultural damages. The worst damage happens to residences. The floodwater enters sanitary sewers through street manholes, and floods basements and lower levels. This flooding is accompanied by major cleanup problems and health hazards, though there is usually no structural damage. More severe floods gain direct entrance to basements, subground living areas, and lower-level garages through surface runoff. This type of flood causes some minor structural damage. Only infrequently do floods enter first floor levels by direct surface runoff. When this does occur, there is usually major damage to structures and contents. In the unincorporated area of Cook County, business and commercial structures are generally located higher than residences and suffer relatively minor flood damage.

Another major type of flood damage is the flooding of highways and local roads. Considerable economic losses result from delays in travel. Flooded roads impede emergency vehicles and vehicles providing necessary goods and services. Schools often are closed because of lack of access.

A third type of flood damage is neighborhood degradation caused by frequent flooding. This is more subtle damage characterized by declining neighborhoods.

Estimates for flood damages are not available for unincorporated areas of Cook County.

2.4 Flood Protection Measures

Many flood protection measures in Cook County have either been installed or planned for construction in the near future. Five of these projects encompass large areas of Cook County. The remaining projects consist of the construction and maintenance of floodwater-retarding structures, channel maintenance, dredging, channel improvements, and debris removal on a specific reach of a stream.

The MSDGC is the implementing agency for two major flood protection measures. The Compensatory Storage Required for New Construction Project covers all areas served by the MSDGC. The Tunnel and Reservoir Plan is operative throughout the North Branch Chicago River watershed and along tributaries of the Little Calumet River.

The DOWR is responsible for flood plain regulations for the watersheds of the North Branch Chicago River, Salt Creek, and Poplar Creek, and for tributaries of the Little Calumet River. The department also provides flood-proofing assistance for the same areas, excluding the Salt Creek watershed.

The COE is responsible for the fifth major flood protection measure. They are doing a restudy dealing with land treatment for the watersheds of the North Branch Chicago River, Salt Creek, and Poplar Creek, and for tributaries of the Little Calumet River.

Specific flood-control measures include the multi-purpose Busse Woods Reservoir, low-flow control dams along the Des Plaines River upstream from Riverside, a dam and reservoir for the purposes of flood control and recreation along Midlothian Creek, and the Sauk Trail Reservoir.

Several of the flood protection measures mentioned are located in incorporated areas or on main stem or tributary reaches that are not within the scope of this study. However, these measures do affect water-surface elevations for streams in the unincorporated areas, and, therefore, were considered in the analyses.

3.0 ENGINEERING METHODS

For the flooding sources studied in detail in the county, standard hydrologic and hydraulic study methods were used to determine the flood hazard data required for this study. Floods having recurrence intervals of 10, 50, 100, and 500 years have been selected as having special significance for flood plain management and for flood insurance premium rates. The analyses reported here reflect current conditions in the watersheds of the flooding sources.

3.1 Hydrologic Analyses

Hydrologic analyses were carried out to establish the peak discharge-frequency relationships for floods of the selected recurrence intervals for each flooding source studied in detail in the county.

Discharges for the 10-, 50-, and 100-year floods for streams studied in detail were computed using the log-Pearson Type III method (Reference 2) for gaged streams and regional equations for ungaged streams (References 3 and 4). The 500-year flood discharges were estimated by straight-line extrapolation.

The USGS stream gages used for the hydrologic analyses for the streams studied in detail in Cook County, Illinois, are presented in Table 1, "USGS Stream Gages."

TABLE 1 - USGS STREAM GAGES

FLOODING SOURCE AND LOCATION	USGS GAGE NUMBER	DRAINAGE AREA (sq. miles)	RECORD (years)
West Fork of North Branch Chicago River at Deerfield, Illinois	05534500	19.7	24
North Branch Chicago River at Niles, Illinois	05536000	100	26
Salt Creek near Arlington Heights, Illinois	05531000	32.5	22
Salt Creek at Western Springs, Illinois	05531500	114	31
Des Plaines River near Gurnee, Illinois	0552800	230	29
Des Plaines River near Des Plaines, Illinois	0552900	359	36
Buffalo Creek near Wheeling, Illinois	05528500	19.4	24
Flag Creek at Willow Springs, Illinois	05533000	16.5	25
Poplar Creek at Elgin, Illinois	05550500	36.3	25
Deer Creek near Chicago Heights, Illinois	05536235	23.1	28
North Creek near Lansing, Illinois	05536270	16.8	28
Butterfield Creek at Flossmoor, Illinois	05536255	23.5	28
Thorn Creek at Thornton, Illinois	05536275	104	28
Thorn Creek at Glenwood, Illinois	05536215	24.7	27
Long Run near Lemont, Illinois	05537500	20.9	25
Tinley Creek near Palos Park, Illinois	05536500	11.2	25
McDonald Creek near Mount Prospect, Illinois	05529500	7.93	24

The results of the hydrologic analyses were submitted to the Illinois State Water Survey (SWS) for review. The 100-year flood discharges computed for the 60 streams studied in detail in the unincorporated areas of Cook County were approved by the SWS and were certified by the DOWR.

A summary of the drainage area-peak discharge relationships for the streams studied by detailed methods is shown in Table 2, "Summary of Discharges."

The 100- and 500-year discharges along Tributary A of Buffalo Creek were adjusted to include interbasin spillage from the Salt Creek watershed. This spillage does not occur during the 10- and 50-year floods. Therefore, on the upstream reach of Tributary A of Buffalo Creek, the 10- and 50-year floods are insignificant.

3.2 Hydraulic Analyses

Analyses of the hydraulic characteristics of the flooding sources studied in detail were carried out to provide estimates of the elevations of floods of the selected recurrence intervals along each of these flooding sources.

The water-surface elevations for the streams studied in detail were computed using either the SCS WSP-2 step-backwater computer program or the COE HEC-2 step-backwater computer program (References 5 and 6). Starting water-surface elevations for the streams studied in detail were determined using corresponding flood elevations on the main stem, using flood profiles from previous studies by the State of Illinois and the SCS, by normal depth computations, and by rating curves. Backwater effects at confluences with larger stream systems are reflected on the Flood Profiles (Exhibit 1).

The type of hydraulic model used and the specific method of determining the starting water-surface elevation for each stream studied in detail is shown in Table 3, "Hydraulic Models."

Cross-section data for the streams studied in detail were obtained by field measurement. All bridges and culverts were surveyed to obtain structural geometry and elevation data.

Roughness coefficients (Manning's "n") for the hydraulic computations were assigned on the basis of field inspection, analyses of photographs, and sound engineering judgment. The ranges of "n"

HYDRAULIC MODELS

values for the channels and overbanks of the 60 streams studied in detail in the county are shown in Table 4, "Roughness Coefficients (Manning's "n")."

Flood profiles were drawn showing computed water-surface elevations to an accuracy of 0.5 foot for floods of the selected recurrence intervals. Locations of selected cross sections used in the hydraulic analyses are shown on the Flood Profiles (Exhibit 1). For stream segments for which a floodway is computed (Section 4.2), selected cross-section locations are also shown on the Flood Boundary and Floodway Map (Exhibit 3).

The approximate flood elevations for Skokie Ditch and Tributary DA of West Branch of Salt Creek were determined by normal depth computations and by using the corresponding elevation on Tributary D of West Branch of Salt Creek, respectively.

All elevations used in this study are referenced to the National Geodetic Vertical Datum of 1929 (NGVD), formerly referred to as Sea Level Datum of 1929. Locations of the elevation reference marks used in the study are shown on the maps.

The hydraulic analyses for this study are based on the effects of unobstructed flow. The flood elevations shown on the profiles are valid only if hydraulic structures remain unobstructed, and dams and other flood control structures operate properly and do not fail.

4.0 FLOOD PLAIN MANAGEMENT APPLICATIONS

A prime purpose of the National Flood Insurance Program is to encourage state and local governments to adopt sound flood plain management programs. Each Flood Insurance Study, therefore, includes a flood boundary map designed to assist communities in developing sound flood plain management measures.

4.1 Flood Boundaries

In order to provide a national standard without regional discrimination, the 100-year flood has been adopted by the FIA as the base flood for purposes of flood plain management measures. The 500-year flood is employed to indicate additional areas of flood risk in the community. For each stream studied in detail, the boundaries of the 100- and 500-year floods have been delineated using the flood elevations determined at each cross section; between cross sections, the

ROUGHNESS COEFFICIENTS (MANNING'S "N")

boundaries were interpolated using topographic maps at a scale of 1:4,800 and 1:24,000 with a contour interval of 2 feet and 10 feet, respectively (References 7 and 8). In cases where the 100- and 500-year flood boundaries are close together, only the 100-year boundary has been shown.

It was determined that certain bridges crossing streams studied by detailed methods would not be included in the backwater analyses due to the minimal effects they would have on flood elevations. In these instances the bridges are shown on the maps, and the location is noted on the profile, but no bridge elevations are given.

Flood boundaries for areas studied by approximate methods were delineated using the Cook County Flood Hazard Boundary Map, USGS Flood Prone Area Maps, and Regulatory Flood Plain Maps (References 9, 10, and 11).

The boundaries of the 100- and 500-year floods are shown on the Flood Boundary and Floodway Map (Exhibit 3). Small areas within the flood boundaries may lie above the flood elevations and, therefore, may not be subject to flooding. Owing to limitations of the map scale and lack of detailed topographic data, such areas are not shown.

4.2 Floodways

Encroachment on flood plains, such as artificial fill, reduces the flood-carrying capacity, increases the flood heights of streams, and increases flood hazards in areas beyond the encroachment itself. One aspect of flood plain management involves balancing the economic gain from flood plain development against the resulting increase in flood hazard. For purposes of the Flood Insurance Program, the concept of a floodway is used as a tool to assist local communities in this aspect of flood plain management. Under this concept, the area of the 100-year flood is divided into a floodway and a floodway fringe. The floodway is the channel of a stream plus any adjacent flood plain areas that must be kept free of encroachment in order that the 100-year flood can be carried without substantial increases in flood heights. Minimum standards of the FIA limit such increases in flood heights to 1.0 foot, provided that hazardous velocities are not produced. However, the State of Illinois has established criteria limiting the increase in flood heights to 0.1 foot. Thus, floodways having no more than a 0.1-foot surcharge have been delineated for this study. The floodways in this report are presented to local agencies as minimum standards that can be adopted or that can be used as a basis for additional studies.

The floodways presented in this study were computed on the basis of equal conveyance reduction from each side of the flood plains. The results of these computations are tabulated at selected cross sections for each stream segment for which a floodway is computed (Table 5).

TABLE 5

FEDERAL EMERGENCY MANAGEMENT AGENCY
Federal Insurance Administration

COOK COUNTY, IL
(UNINCORPORATED AREAS)

FLOODWAY DATA

FLOSSMOOR DITCH AND TRIBUTARY A OF FLOSSMOOR DITCH

As shown on the Flood Boundary and Floodway Map (Exhibit 3), the floodway widths were determined at cross sections; between cross sections, the boundaries were interpolated. In cases where the boundaries of the floodway and the 100-year flood are either close together or collinear, only the floodway boundary has been shown.

Portions of certain floodways on the following streams extend beyond the unincorporated Cook County boundaries: Salt Creek, Tributary C of Salt Creek, Tributary D of West Branch of Salt Creek, Higgins Creek, Silver Creek, Poplar Creek, Schaumburg Branch of Poplar Creek, Butterfield Creek, Thorn Creek, North Creek, Midlothian Creek, Tributary A of Illinois and Michigan Canal, Marley Creek, and Flossmoor Ditch.

Near the mouths of streams studied in detail, floodway computations are made without regard to flood elevations on the receiving water body. Therefore, "With Floodway" elevations presented in Table 5 for certain downstream cross sections of Tributary A of West Fork of North Branch Chicago River and North Creek are lower than the regulatory flood elevations in that area, which must take into account the 100-year flooding due to backwater from other sources.

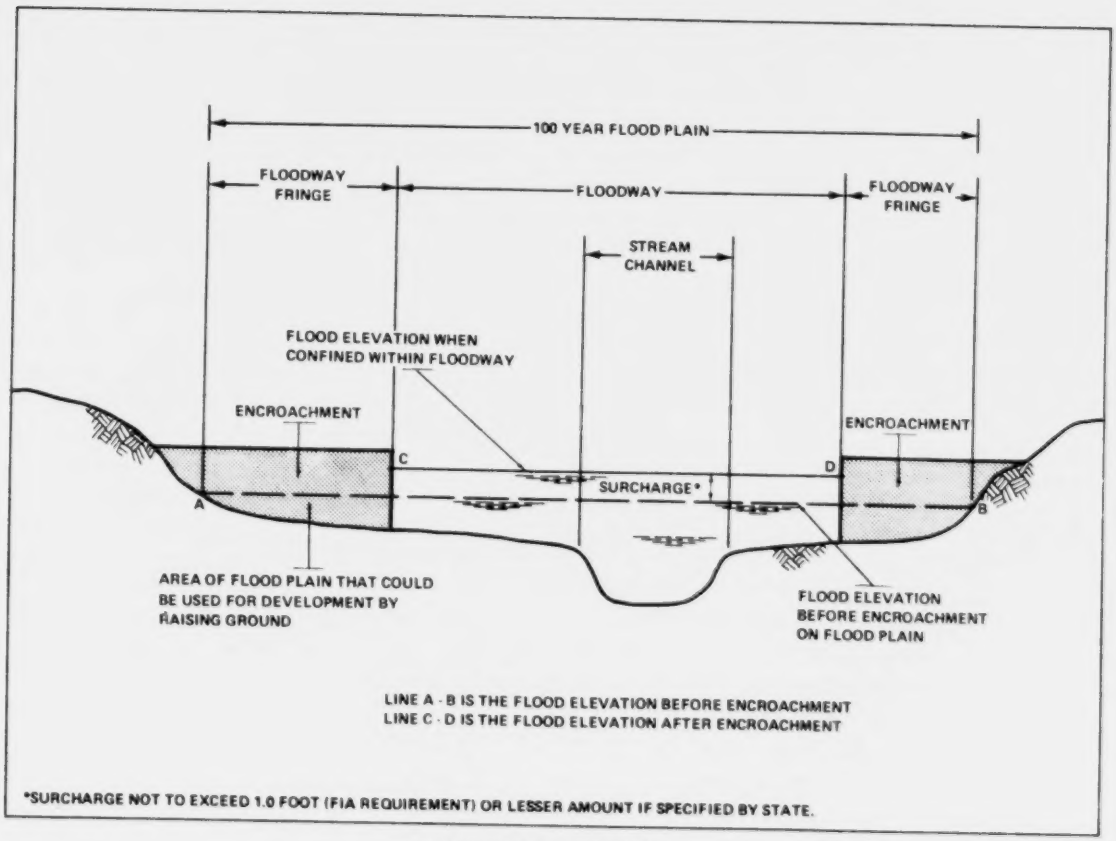
The area between the floodway and the boundary of the 100-year flood is termed the floodway fringe. The floodway fringe thus encompasses the portion of the flood plain that could be completely obstructed without increasing the water-surface elevation of the 100-year flood by more than 1.0 foot at any point. Typical relationships between the floodway and the floodway fringe and their significance to flood plain development are shown in Figure 2.

5.0 INSURANCE APPLICATION

In order to establish actuarial insurance rates, the FIA has developed a process to transform the data from the engineering study into flood insurance criteria. This process includes the determination of reaches, Flood Hazard Factors (FHFs), and flood insurance zone designations for each flooding source affecting the unincorporated areas of Cook County.

5.1 Reach Determinations

Reaches are defined as lengths of watercourses having relatively the same flood hazard, based on the average weighted difference in water-surface elevations between the 10- and 100-year floods. This difference does not have a variation greater than that indicated in the following table for more than 20 percent of the reach.



FLOODWAY SCHEMATIC

Figure 2

Average Difference Between 10- and 100-Year Floods	Variation
Less than 2 feet	0.5 foot
2 to 7 feet	1.0 foot
7.1 to 12 feet	2.0 feet
More than 12 feet	3.0 feet

The locations of the reaches determined for the flooding sources of the unincorporated areas of Cook County are shown on the Flood Profiles (Exhibit 1) and are summarized in the Flood Insurance Zone Data Table (Table 6).

FLOODING SOURCE	PANEL[1]	ELEVATION DIFFERENCE[2] BETWEEN 1.0% (100-YEAR) FLOOD AND			FHF	ZONE	BASE FLOOD ELEVATION[3] (NGVD)
		10% (10 YR.)	2% (50 YR.)	0.2% (500 YR.)			
West Fork of North Branch Chicago River

5.2 Flood Hazard Factors

The FHF is the FIA device used to correlate flood information with insurance rate tables. Correlations between property damage from floods and their FHFs are used to set actuarial insurance premium rate tables based on FHFs from 005 to 200.

The FHF for a reach is the average weighted difference between the 10- and 100-year flood water-surface elevations expressed to the nearest 0.5 foot, and shown as a three-digit code. For example, if the difference between water-surface elevations of the 10- and 100-year floods is 0.7 foot, the FHF is 005; if the difference is 1.4 feet, the FHF is 015; if the difference is 5.0 feet, the FHF is 050. When the difference between the 10- and 100-year water-surface elevations is greater than 10.0 feet, accuracy for the FHF is to the nearest foot.

5.3 Flood Insurance Zones

After the determination of reaches and their respective FHFs, the entire unincorporated area of Cook County was divided into zones, each having a specific flood potential or hazard. Each zone was assigned one of the following flood insurance zone designations:

Zone A:	Special Flood Hazard Areas inundated by the 100-year flood, determined by approximate methods; no base flood elevations shown or FHFs determined.
Zones A1, A2, A3, A4, A5, A6, A7, A12, A13:	Special Flood Hazard Areas inundated by the 100-year flood, determined by detailed methods; base flood elevations shown, and zones subdivided according to FHF.
Zone B:	Areas between the Special Flood Hazard Area and the limits of the 500-year flood, including areas of the 500-year flood plain that are protected from the 100-year flood by dike, levee, or other water control structure; also, areas subject to certain types of 100-year shallow flooding where depths are less than 1.0 foot; and areas subject to 100-year flooding from sources with drainage areas less than 1 square mile. Zone B is not subdivided.

Zone C: Areas of minimal flooding.

Table 6, "Flood Insurance Zone Data," summarizes the flood elevation differences, FHFs, flood insurance zones, and base flood elevations for the flooding sources studied in detail in the unincorporated areas of Cook County.

5.4 Flood Insurance Rate Map Description

The Flood Insurance Rate Map for the unincorporated areas of Cook County is, for insurance purposes, the principal result of the Flood Insurance Study. This map (published separately) contains the official delineation of flood insurance zones and base flood elevation lines. Base flood elevation lines show the locations of the expected whole-foot water-surface elevations of the base (100-year) flood. This map is developed in accordance with the latest flood insurance map preparation guidelines published by the FIA.

6.0 OTHER STUDIES

There are eight recent reports which discuss flood problems and their potential solutions for streams which are located in, or which have an effect on flood profiles in the unincorporated areas of Cook County (References 12 through 19). These reports were prepared by many agencies, including the State of Illinois, the COE, the SCS, the MSDGC, the U. S. Forest Service, the Cook County Forest Preserve District, individual municipalities, and watershed steering committees. Flood profiles shown in this Flood Insurance Study agree with the latest profiles prepared by other agencies in the State of Illinois.

Flood profiles and flood boundaries shown in this study for the unincorporated areas of Cook County agree with those presented in the flood insurance studies performed for incorporated areas within the county. The studies for these communities have been published, or are being prepared for publication, by the Federal Insurance Administration of the Federal Emergency Management Agency.

This study is authoritative for purposes of the Flood Insurance Program, and the data presented here either supersede or are compatible with previous determinations.

7.0 LOCATION OF DATA

Survey, hydrologic, hydraulic, and other pertinent data used in this study can be obtained by contacting the office of the Insurance and Mitigation Division of the Federal Emergency Management Agency, Regional Director, Region V Office, 1 North Dearborn Street, Room 540, Chicago, Illinois 60602.
